4.3 Transforms

Transforms often provide us convenient ways with regard to certain mathematical manipulations.

The transform, in other words, the moment generating function (MGF), of a r.v. $X$ is defined as

$$M_X(s) = E[e^{sX}].$$

Discrete case MGF: $M_X(s) = \sum_x e^{sx}p_X(x)$
Continuous case MGF: $M_X(s) = \int_{-\infty}^{\infty} e^{sx}f_X(x)\,dx$

Ex: MGF of a Poisson r.v.

Ex: MGF of an exponential r.v.

Ex: MGF of a linear function of a r.v.

Ex: MGF of a Gaussian random variable with mean $\mu$ and variance $\sigma^2$

Ex: Using the MGF of the Gaussian, and the property we just proved about the transform of a linear function of a random variable, show that a linear function of a Gaussian r.v. is also Gaussian.

4.3.1 Computation of Moments from Transforms

The name moment generating function follows from the following property.

$$E[X^n] = \frac{d^n}{ds^n}M_X(s) |_{s=0}$$

Proof:
Ex: Mean and variance of an exponential r.v.

Note: The transform \( M_X(s) \) of a r.v. \( X \) uniquely determines the PDF of \( X \). That is, one can always find \( f_X(x) \) from \( M_X(s) \).

4.3.2 Mixture of two distributions

Ex: The length in KBytes of IP packets received at a switch are, with 80 \% probability, exponentially distributed with mean 10, and with 20 \% probability, exponentially distributed with mean 100. Determine the MGF of the length of a randomly (uniformly) selected packet.

4.3.3 Sums of Independent R.V.s

When \( X_1, X_2, \ldots, X_k \) are independent r.v.s, the MGF of their sum \( Y = \sum_{i=1}^k X_i \) has a simple form. In deriving it, one may interpret \( e^{sX_i} \) as a function of \( X_i \).

Ex: Sum of independent Poisson r.v.s

Ex: The sum of two independent Gaussian random variables is Gaussian. Let \( X \sim \mathcal{N}(\mu_1, \sigma_1^2) \), and \( Y \sim \mathcal{N}(\mu_2, \sigma_2^2) \).
