

CHAPTER 4

REQUIREMENTS ANALYSIS

4.1 SYSTEMS ENGINEERING PROCESS INPUTS

The inputs to the process include the customer's requirements and the project constraints. Requirements relate directly to the performance characteristics of the system being designed. They are the stated life-cycle customer needs and objectives for the system, and they relate to how well the system will work in its intended environment.

Constraints are conditions that exist because of limitations imposed by external interfaces, project support, technology, or life cycle support systems. Constraints bound the development teams' design opportunities.

Requirements are the primary focus in the systems engineering process because the process's primary purpose is to transform the requirements into designs. The process develops these designs within

the constraints. They eventually must be verified to meet both the requirements and constraints.

Types of Requirements

Requirements are categorized in several ways. The following are common categorizations of requirements that relate to technical management:

Customer Requirements: Statements of fact and assumptions that define the expectations of the system in terms of mission objectives, environment, constraints, and measures of effectiveness and suitability (MOE/MOS). The customers are those that perform the eight primary functions of systems engineering (Chapter 1), with special emphasis on the operator as the key customer. Operational requirements will define the basic need and, at a minimum, answer the questions posed in Figure 4-1.

Operational distribution or deployment: Where will the system be used?

Mission profile or scenario: How will the system accomplish its mission objective?

Performance and related parameters: What are the critical system parameters to accomplish the mission?

Utilization environments: How are the various system components to be used?

Effectiveness requirements: How effective or efficient must the system be in performing its mission?

Operational life cycle: How long will the system be in use by the user?

Environment: What environments will the system be expected to operate in an effective manner?

Figure 4-1. Operational Requirements – Basic Questions

Functional Requirements: The necessary task, action or activity that must be accomplished. Functional (what has to be done) requirements identified in requirements analysis will be used as the top-level functions for functional analysis.

Performance Requirements: The extent to which a mission or function must be executed; generally measured in terms of quantity, quality, coverage, timeliness or readiness. During requirements analysis, performance (how well does it have to be done) requirements will be interactively developed across all identified functions based on system life cycle factors; and characterized in terms of the degree of certainty in their estimate, the degree of criticality to system success, and their relationship to other requirements.

Design Requirements: The “build to,” “code to,” and “buy to” requirements for products and “how to execute” requirements for processes expressed in technical data packages and technical manuals.

Derived Requirements: Requirements that are implied or transformed from higher-level requirement. For example, a requirement for long range or high speed may result in a design requirement for low weight.

Allocated Requirements: A requirement that is established by dividing or otherwise allocating a high-level requirement into multiple lower-level requirements. Example: A 100-pound item that consists of two subsystems might result in weight requirements of 70 pounds and 30 pounds for the two lower-level items.

Attributes of Good Requirements

The attributes of good requirements include the following:

- A requirement must be achievable. It must reflect need or objective for which a solution is technically achievable at costs considered affordable.

- It must be verifiable—that is, not defined by words such as excessive, sufficient, resistant, etc. The expected performance and functional utility must be expressed in a manner that allows verification to be objective, preferably quantitative.
- A requirement must be unambiguous. It must have but one possible meaning.
- It must be complete and contain all mission profiles, operational and maintenance concepts, utilization environments and constraints. All information necessary to understand the customer’s need must be there.
- It must be expressed in terms of need, not solution; that is, it should address the “why” and “what” of the need, not how to do it.
- It must be consistent with other requirements. Conflicts must be resolved up front.
- It must be appropriate for the level of system hierarchy. It should not be too detailed that it constrains solutions for the current level of design. For example, detailed requirements relating to components would not normally be in a system-level specification.

4.2 REQUIREMENTS ANALYSIS

Requirements analysis involves defining customer needs and objectives in the context of planned customer use, environments, and identified system characteristics to determine requirements for system functions. Prior analyses are reviewed and updated, refining mission and environment definitions to support system definition.

Requirements analysis is conducted iteratively with functional analysis to optimize performance requirements for identified functions, and to verify that synthesized solutions can satisfy customer requirements. The purpose of Requirements Analysis is to:

- Refine customer objectives and requirements;
- Define initial performance objectives and refine them into requirements;
- Identify and define constraints that limit solutions; and
- Define functional and performance requirements based on customer provided measures of effectiveness.

In general, Requirements Analysis should result in a clear understanding of:

- Functions: What the system has to do,
- Performance: How well the functions have to be performed,
- Interfaces: Environment in which the system will perform, and
- Other requirements and constraints.

The understandings that come from requirements analysis establish the basis for the functional and physical designs to follow. Good requirements

analysis is fundamental to successful design definition.

Inputs

Typical inputs include customer needs and objectives, missions, MOE/MOS, environments, key performance parameters (KPPs), technology base, output requirements from prior application of SEP, program decision requirements, and suitability requirements. (See Figure 4-2 for additional considerations.)

Input requirements must be comprehensive and defined for both system products and system processes such as development, manufacturing, verification, deployment, operations, support, training and disposal (eight primary functions).

Role of Integrated Teams

The operator customers have expertise in the operational employment of the product or item being developed. The developers (government and contractor) are not necessarily competent in the operational aspects of the system under development. Typically, the operator's need is neither clearly nor completely expressed in a way directly

Figure 4-2. Inputs to Requirements Analysis

usable by developers. It is unlikely that developers will receive a well-defined problem from which they can develop the system specification. Thus, teamwork is necessary to understand the problem and to analyze the need. It is imperative that customers are part of the definition team.

On the other hand, customers often find it easier to describe a system that attempts to solve the problem rather than to describe the problem itself. Although these “solutions” may be workable to some extent, the optimum solution is obtained through a proper technical development effort that properly balances the various customer mission objectives, functions, MOE/MOS, and constraints. An integrated approach to product and process development will balance the analysis of requirements by providing understanding and accommodation among the eight primary functions.

Requirements Analysis Questions

Requirements Analysis is a process of inquiry and resolution. The following are typical questions that can initiate the thought process:

- What are the reasons behind the system development?
- What are the customer expectations?
- Who are the users and how do they intend to use the product?
- What do the users expect of the product?
- What is their level of expertise?
- With what environmental characteristics must the system comply?
- What are existing and planned interfaces?
- What functions will the system perform, expressed in customer language?
- What are the constraints (hardware, software, economic, procedural) to which the system must comply?

- What will be the final form of the product: such as model, prototype, or mass production?

This list can start the critical, inquisitive outlook necessary to analyze requirements, but it is only the beginning. A tailored process similar to the one at the end of this chapter must be developed to produce the necessary requirements analysis outputs.

4.3 REQUIREMENTS ANALYSIS OUTPUTS

The requirements that result from requirements analysis are typically expressed from one of three perspectives or views. These have been described as the Operational, Functional, and Physical views. All three are necessary and must be coordinated to fully understand the customers’ needs and objectives. All three are documented in the decision database.

Operational View

The Operational View addresses how the system will serve its users. It is useful when establishing requirements of “how well” and “under what condition.” Operational view information should be documented in an operational concept document that identifies:

- Operational need definition,
- System mission analysis,
- Operational sequences,
- Operational environments,
- Conditions/events to which a system must respond,
- Operational constraints on system,
- Mission performance requirements,
- User and maintainer roles (defined by job tasks and skill requirements or constraints),

- Structure of the organizations that will operate, support and maintain the system, and
- Operational interfaces with other systems.

Analyzing requirements requires understanding the operational and other life cycle needs and constraints.

Functional View

The Functional View focuses on WHAT the system must do to produce the required operational behavior. It includes required inputs, outputs, states, and transformation rules. The functional requirements, in combination with the physical requirements shown below, are the primary sources of the requirements that will eventually be reflected in the system specification. Functional View information includes:

- System functions,
- System performance,
 - Qualitative — how well
 - Quantitative — how much, capacity
 - Timeliness — how often
- Tasks or actions to be performed,
- Inter-function relationships,
- Hardware and software functional relationships,
- Performance constraints,
- Interface requirements including identification of potential open-system opportunities (potential standards that could promote open systems should be identified),
- Unique hardware or software, and
- Verification requirements (to include inspection, analysis/simulation, demo, and test).

Physical View

The Physical View focuses on HOW the system is constructed. It is key to establishing the physical interfaces among operators and equipment, and technology requirements. Physical View information would normally include:

- Configuration of System:
 - Interface descriptions,
 - Characteristics of information displays and operator controls,
 - Relationships of operators to system/physical equipment, and
 - Operator skills and levels required to perform assigned functions.
- Characterization of Users:
 - Handicaps (special operating environments), and
 - Constraints (movement or visual limitations).
- System Physical Limitations:
 - Physical limitations (capacity, power, size, weight),
 - Technology limitations (range, precision, data rates, frequency, language),
 - Government Furnished Equipment (GFE), Commercial-Off-the-Shelf (COTS), Nondevelopmental Item (NDI), reusability requirements, and
 - Necessary or directed standards.

4.4 SUMMARY POINTS

- An initial statement of a need is seldom defined clearly.
- A significant amount of collaboration between various life cycle customers is necessary to produce an acceptable requirements document.
- Requirements are a statement of the problem to be solved. Unconstrained and nonintegrated requirements are seldom sufficient for designing a solution.

- Because requirements from different customers will conflict, constraints will limit options, and resources are not unlimited; trade studies must be accomplished in order to select a balanced set of requirements that provide feasible solutions to customer needs.

SUPPLEMENT 4-A

A PROCEDURE FOR REQUIREMENTS ANALYSIS

The following section provides a list of tasks that represents a plan to analyze requirements. Part of this notional process is based on the 15 requirements analysis tasks listed in IEEE P1220. This industry standard and others should be consulted when preparing engineering activities to help identify and structure appropriate activities.

As with all techniques, the student should be careful to tailor; that is, add or subtract, as suits the particular system being developed. Additionally, these tasks, though they build on each other, should not be considered purely sequential. Every task contributes understanding that may cause a need to revisit previous task decisions. This is the nature of all System Engineering activities.

Preparation: Establish and Maintain Decision Database

When beginning a systems engineering process, be sure that a system is in place to record and manage the decision database. The decision database is an historical database of technical decisions and

requirements for future reference. It is the primary means for maintaining requirements traceability. This database decision management system must be developed or the existing system must be reviewed and upgraded as necessary to accommodate the new stage of product development. A key part of this database management system is a Requirements Traceability Matrix that maps requirements to subsystems, configuration items, and functional areas.

This must be developed, updated, and reissued on a regular basis. All requirements must be recorded. ***Remember: If it is not recorded, it cannot be an approved requirement!***

The 15 Tasks of IEEE P1220

The IEEE Systems Engineering Standard offers a process for performing Requirements Analysis that comprehensively identifies the important tasks that must be performed. These 15 task areas to be analyzed follow and are shown in Figure 4-3.

1. Customer expectations	9. Life cycle
2. Project and enterprise constraints	10. Functional requirements
3. External constraints	11. Performance requirements
4. Operational scenarios	12. Modes of operation
5. Measure of effectiveness (MOEs)	13. Technical performance measures
6. System boundaries	14. Physical characteristics
7. Interfaces	15. Human systems integration
8. Utilization environments	

Figure 4-3. IEEE P1220 Requirements Analysis Task Areas

Task 1. Customer Expectations

Define and quantify customer expectations. They may come from any of the eight primary functions, operational requirements documents, mission needs, technology-based opportunity, direct communications with customer, or requirements from a higher system level. The purpose of this task is to determine what the customer wants the system to accomplish, and how well each function must be accomplished. This should include natural and induced environments in which the product(s) of the system must operate or be used, and constraints (e.g. funding, cost, or price objectives, schedule, technology, nondevelopmental and reusable items, physical characteristics, hours of operation per day, on-off sequences, etc.).

Task 2. Project and Enterprise Constraints

Identify and define constraints impacting design solutions. Project specific constraints can include:

- Approved specifications and baselines developed from prior applications of the Systems Engineering Process,
- Costs,
- Updated technical and project plans,
- Team assignments and structure,
- Control mechanisms, and
- Required metrics for measuring progress.

Enterprise constraints can include:

- Management decisions from a preceding technical review,
- Enterprise general specifications,
- Standards or guidelines,
- Policies and procedures,
- Domain technologies, and

- Physical, financial, and human resource allocations to the project.

Task 3. External Constraints

Identify and define external constraints impacting design solutions or implementation of the Systems Engineering Process activities. External constraints can include:

- Public and international laws and regulations,
- Technology base,
- Compliance requirements: industry, international, and other general specifications, standards, and guidelines which require compliance for legal, interoperability, or other reasons,
- Threat system capabilities, and
- Capabilities of interfacing systems.

Task 4. Operational Scenarios

Identify and define operational scenarios that scope the anticipated uses of system product(s). For each operational scenario, define expected:

- Interactions with the environment and other systems, and
- Physical interconnectivities with interfacing systems, platforms, or products.

Task 5. Measures of Effectiveness and Suitability (MOE/MOS)

Identify and define systems effectiveness measures that reflect overall customer expectations and satisfaction. MOEs are related to how well the system must perform the customer's mission. Key MOEs include mission performance, safety, operability, reliability, etc. MOSs are related to how well the system performs in its intended environment and includes measures of supportability, maintainability, ease of use, etc.

Task 6. System Boundaries

Define system boundaries including:

- Which system elements are under design control of the performing activity and which fall outside of their control, and
- The expected interactions among system elements under design control and external and/or higher-level and interacting systems outside the system boundary (including open systems approaches).

Task 7. Interfaces

Define the functional and physical interfaces to external or higher-level and interacting systems, platforms, and/or products in quantitative terms (include open systems approach). Functional and physical interfaces would include mechanical, electrical, thermal, data, control, procedural, and other interactions. Interfaces may also be considered from an internal/external perspective. Internal interfaces are those that address elements inside the boundaries established for the system addressed. These interfaces are generally identified and controlled by the contractor responsible for developing the system. External interfaces, on the other hand, are those which involve entity relationships outside the established boundaries, and these are typically defined and controlled by the government.

Task 8. Utilization Environments

Define the environments for each operational scenario. All environmental factors (natural or induced) which may impact system performance must be identified and defined. Environmental factors include:

- Weather conditions (e.g., rain, snow, sun, wind, ice, dust, fog),
- Temperature ranges,
- Topologies (e.g., ocean, mountains, deserts, plains, vegetation),

- Biological (e.g., animal, insects, birds, fungi),
- Time (e.g., dawn, day, night, dusk), and
- Induced (e.g., vibration, electromagnetic, chemical).

Task 9. Life Cycle Process Concepts

Analyze the outputs of tasks 1-8 to define key life cycle process requirements necessary to develop, produce, test, distribute, operate, support, train, and dispose of system products under development. Use integrated teams representing the eight primary functions. Focus should be on the cost drivers and higher risk elements that are anticipated to impact supportability and affordability over the useful life of the system.

Task 10. Functional Requirements

Define what the system must accomplish or must be able to do. Functions identified through requirements analysis will be further decomposed during functional analysis and allocation.

Task 11. Performance Requirements

Define the performance requirements for each higher-level function performed by the system. Primary focus should be placed on performance requirements that address the MOEs, and other KPPs established in test plans or identified as interest items by oversight authorities.

Task 12. Modes of Operation

Define the various modes of operation for the system products under development. Conditions (e.g., environmental, configuration, operational, etc.) that determine the modes of operation should be included in this definition.

Task 13. Technical Performance Measures (TPMs)

Identify the key indicators of system performance that will be tracked during the design process. Selection of TPMs should be limited to critical

technical thresholds and goals that, if not met, put the project at cost, schedule, or performance risk. TPMs involve tracking the actual versus planned progress of KPPs such that the manager can make judgments about technical progress on a by-exception basis. To some extent TPM selection is phase dependent. They must be reconsidered at each systems engineering process step and at the beginning of each phase.

Task 14. Physical Characteristics

Identify and define required physical characteristics (e.g., color, texture, size, weight, buoyancy) for the system products under development. Identify which physical characteristics are true constraints and which can be changed, based on trade studies.

Task 15. Human Factors

Identify and define human factor considerations (e.g., physical space limits, climatic limits, eye movement, reach, ergonomics) which will affect operation of the system products under development. Identify which human systems integration are constraints and which can be changed based on trade studies.

Follow-on Tasks

The follow-on tasks are related to the iterative nature of the Systems Engineering Process:

Integrate Requirements:

Take an integrated team approach to requirements determination so that conflicts among and between requirements are resolved in ways that result in design requirements that are balanced in terms of both risk and affordability.

Validate Requirements:

During Functional Analysis and Allocation, validate that the derived functional and performance can be traced to the operational requirements.

Verify Requirements:

- Coordinate design, manufacturing, deployment and test processes,
- Ensure that requirements are achievable and testable,
- Verify that the design-to-cost goals are achievable, and
- Verify that the functional and physical architectures defined during Functional Analysis/ Allocation and Synthesis meet the integrated technical, cost, and schedule requirements within acceptable levels of risk.
